Bellman-Ford's Search

Bellman-Ford's Search

Richard Ernest Bellman
1925-2003

Lester Randolph Ford, Jr
1927-2017

Bellman-Ford's Search

- It finds the shortest path from a source node to all other nodes in a graph for any positive or negative edge cost values in a digraph **or** tells whether the graph contains **negative cycles**.
- It may consider nodes that are already expanded as long as they are reachable with a less cost.
- **Dynamic programming** algorithm
 - Optimal Substructure

Bellman-Ford's Search

- Cycles with negative total weights

- Negative edges make the shortest path problem harder.
- Negative cycles make the path problem non-traceable.

Bellman-Ford's Search

- **Claim:** If G has **no** negative cycles, then there is a shortest path from s to t that is simple (i.e. does not repeat nodes), and hence has at most $n - 1$ edges.

```

for (each vertex v in Graph) {
    dist[v] =  $+\infty$ ;
    previous[v] = null;
}
dist[source] = 0;
counter = 0;
for (i=0; i < numberOfVertices; i++) {
    for (each edge (u, v) with cost w)           // A
        if (dist[u] + w < dist[v]) {
            dist[v] = dist[u] + w;
            previous[v] = u;
            counter++;
        }
    if (counter==0) break;
}
if (counter==0) then there is no negative cycles
else {
    run loop A again
    if (counter==0) then there is no negative cycles
    else there is a negative cycle
}

```

`No negative cycles`

Bellman-Ford's Search

- **Complete?**
 - Yes.
- **Optimal?**
 - Yes, if the state space doesn't contain cycles with negative total values.
- **Complexity** in terms of number of vertices: n and number of edges: m
 - Time complexity: $O(m * n) = O(n^3)$, note: $m = O(n^2)$.
 - Space complexity: $O(n)$

Self-Test

Question: How many invocations of a single source shortest-path subroutine are needed to solve the all-pairs shortest path problem? [n = # of vertices]

- a) 1
- b) $n-1$
- c) n
- d) n^2
