1. ASTEROIDS – Physics

1.1. Velocity – Moving Along Vectors

- In most games, sprite movement is done according to some vector and speed.
- The direction of the vector is usually determined by user input, collision reaction and reflection.
- The movement speed is determined by a “speed” variable and not by the direction vector's length.
- **Velocity = Normalized Direction * speed**
- Moving a sprite is done by changing its current position (which will later result in a new translation matrix).
- Getting the next position of a sprite whose speed is S and direction vector is V:
- Next Position = $S * V * \text{TimeStep} + \text{Current Position}$
 - The mathematical formula of the above equation is:
 - $\text{Pos} = V * t + \text{Pos}_0$. The only difference is that in real time simulation, Pos_0 represents the last frame's position.
- Example:
 - T is a 2D point located at (0;0)
 - Direction vector is (0.31 ; 0.95) (Normalized, explained later).
 - Its speed value is 2.
 - Assume the TimeStep is 1.0 second (In games, the TimeStep is the frame's frame time).
 - Frame 0:
 - $X_0 = 0$
 - $Y_0 = 0$
 - Frame 1:
 - $X_1 = \text{Direction}(X) * \text{speed} * \text{ts} + X_0 = 0.31 * 2 * 1 + 0 = 0.62$
 - $Y_1 = \text{Direction}(Y) * \text{speed} * \text{ts} + Y_0 = 0.95 * 2 * 1 + 0 = 1.9$
 - Frame 2:
 - $X_2 = \text{Direction}(X) * \text{speed} * \text{ts} + X_1 = 0.31 * 2 * 1 + 0.62 = 1.24$
 - $Y_2 = \text{Direction}(Y) * \text{speed} * \text{ts} + Y_1 = 0.95 * 2 * 1 + 1.9 = 3.8$
 - Frame 3:
 - $X_3 = \text{Direction}(X) * \text{speed} * \text{ts} + X_2 = 0.31 * 2 * 1 + 1.24 = 1.86$
 - $Y_3 = \text{Direction}(Y) * \text{speed} * \text{ts} + Y_2 = 0.95 * 2 * 1 + 3.8 = 5.7$

- As long as the direction vector isn't changed, the sprite will keep moving in the same direction (Unless its speed is set to 0).
- On the other hand, if the speed's value goes from being positive to negative, the sprite direction will become the opposite of its own direction vector.
- Note that in most games, the direction vector is normalized, and the object's movement speed is determined by the “speed” value.
- This normalization, which separates the object's direction from its speed, allows us to move an object in any direction at a constant speed.
 - The direction vector's only responsibility is to direct the object.
 - And the object's speed is controlled only by the speed value.
 - Keeping the speed value “2” for example will ensure that that particular object will move 2 units per second no matter what its direction vector is (as long as that direction vector is normalized).

1.2. Acceleration

- Object's velocity doesn't have to be constant in games.
- It can be altered by adding the acceleration element
- The acceleration affects the velocity the same way the velocity affects the position.
- In games, the player usually can control the acceleration of objects, which will implicitly change the objects' velocity and eventually position.
- Getting the next position of a sprite whose velocity is V and acceleration is A :
- Next Position = $\frac{1}{2} A * \text{TimeStep} * \text{TimeStep} + V * \text{TimeStep} + \text{Current Position}$
 - The mathematical formula the above equation is:
 - $\text{Pos}_1 = \frac{1}{2} A * t * t + V_0 * t + \text{Pos}_0$.
The only difference is that in real time simulation, Pos_0 represents last frame's position, V_0 represents last frame's velocity and Pos_1 represents the current frame's position.
 - $V_1 = A * t + V_0$. V_1 is the current frame's velocity and V_0 is last frame's velocity.
 - Note that the speed value (used previously) doesn't exist anymore. This is because the change in velocity is affected by the acceleration, and not by a hard-coded “speed” value.
- Example:
 - T is a 2D point located at (0;0),
 - Velocity is (0, 0) (The object is initially not moving)
 - Its acceleration is (3, 2) during frame 1 and frame 2, then it goes back to (0, 0) in frame 3. (This can be the result of the player pressing the “forward” button during frame 2 and 3)
 - Assume the TimeStep is 1.0 second.

Frame 0:

- $X_0 = 0$
- $Y_0 = 0$

○ Frame 1:

- $X_1 = \frac{1}{2}A_x * t_s^2 + V_{0_x} * t_s + X_0 = 0.5 * 3 * 1^2 + 0 * 1 + 0 = 1.5$
- $Y_1 = \frac{1}{2}A_y * t_s^2 + V_{0_y} * t_s + Y_0 = 0.5 * 2 * 1^2 + 0 * 1 + 0 = 1$
- $V_{1_x} = A_x * t_s + V_{0_x} = 3 * 1 + 0 = 3$
- $V_{1_y} = A_y * t_s + V_{0_y} = 2 * 1 + 0 = 2$

○ Frame 2:

- $X_2 = \frac{1}{2}A_x * t_s^2 + V_{1_x} * t_s + X_1 = 0.5 * 3 * 1^2 + 3 * 1 + 1.5 = 6$
- $Y_2 = \frac{1}{2}A_y * t_s^2 + V_{1_y} * t_s + Y_1 = 0.5 * 2 * 1^2 + 2 * 1 + 1 = 4$
- $V_{2_x} = A_x * t_s + V_{1_x} = 3 * 1 + 3 = 6$
- $V_{2_y} = A_y * t_s + V_{1_y} = 2 * 1 + 2 = 4$

○ Frame 3:

- $X_3 = \frac{1}{2}A_x * t_s^2 + V_{2_x} * t_s + X_2 = 0.5 * 0 * 1^2 + 6 * 1 + 6 = 12$
- $Y_3 = \frac{1}{2}A_y * t_s^2 + V_{2_y} * t_s + Y_2 = 0.5 * 0 * 1^2 + 4 * 1 + 4 = 8$
- $V_{3_x} = A_x * t_s + V_{2_x} = 0 * 1 + 6 = 6$
- $V_{3_y} = A_y * t_s + V_{2_y} = 0 * 1 + 4 = 4$
